

Age Spots and Pigmentation

The skin you are wearing today is the result of a mix of factors, both environmental and genetic.

That great tan you were chasing? Sun exposure and the use of tanning beds accelerate the natural aging process and damage the skin.

Discoloured spots, usually on the hands, shoulders, arms and face, can begin to appear as the skin ages.

They are an excess production of melanin, the skin's natural colourant, and occur deep within the skin.

These areas of hyperpigmentation can be a source of frustration or self-consciousness for some people.

Laser addresses age spots by penetrating beneath the surface of the skin and breaking down patches of pigment at a cellular level.

The treatment is safe and effective. Your clinician will take into account relevant factors including the location of the spots, your skin tone and the extent of damage to the area when designing your treatment.
